Definitions of Managed Objects  
for Remote Ping, Traceroute, and Lookup Operations

Status of This Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Abstract

This memo defines Management Information Bases (MIBs) for performing ping, traceroute, and lookup operations at a host. When managing a network, it is useful to be able to initiate and retrieve the results of ping or traceroute operations when they are performed at a remote host. A lookup capability is defined in order to enable resolution of either an IP address to a DNS name or a DNS name to an IP address at a remote host.

Currently, there are several enterprise-specific MIBs for performing remote ping or traceroute operations. The purpose of this memo is to define a standards-based solution to enable interoperability.

## 1. Introduction

This document defines standards-based MIB modules for performing specific remote operations. The remote operations defined by this document consist of the ping, traceroute, and lookup functions.

Ping and traceroute are two very useful functions for managing networks. Ping is typically used to determine whether a path exists between two hosts, whereas traceroute shows an actual path.

Both ping and traceroute yield round-trip times measured in milliseconds. These times can be used as a rough approximation for network transit time.

The lookup functions considered in this document are the equivalents of name to address conversion functions such as `gethostbyname()`/`gethostbyaddr()` and `getaddrinfo()`/`getnameinfo()`.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

### 1.1. Ping

Ping is usually implemented using the Internet Control Message Protocol (ICMP) "ECHO" facility. It is also possible to implement a ping capability using alternate methods, including the following:

- o Using the UDP echo port (7), if supported.

This is defined by RFC 862 [RFC862].

- o Timing a Simple Network Management Protocol (SNMP) query.
- o Timing a TCP connect attempt.

In general, almost any request/response flow can be used to generate a round-trip time. Often, many of the non-ICMP ECHO facility methods stand a better chance of yielding a good response (not timing out, for example) since some routers don't honor Echo Requests (timeout situation) or are handled at lower priority, thus possibly giving false indications of round trip times.

Note that almost any of the various methods used for generating a round-trip time can be considered a form of system attack when used excessively. Sending a system request too often can negatively effect its performance. Attempting to connect to what is supposed to be an unused port can be very unpredictable. There are tools that attempt to connect to a range of TCP ports to test that any receiving server can handle erroneous connection attempts.

It is also important to a management application using a remote ping capability to know which method is being used. Different methods will yield different response times, since the protocol and resulting processing will be different. It is RECOMMENDED that the ping capability defined within this memo be implemented using the ICMP Echo Facility.

## 1.2. Traceroute

Traceroute is usually implemented by transmitting a series of probe packets with increasing time-to-live values. A probe packet is a UDP datagram encapsulated into an IP packet. Each hop in a path to the target (destination) host rejects the probe packet (probe's TTL too small) until its time-to-live value becomes large enough for the probe to be forwarded. Each hop in a traceroute path returns an ICMP message that is used to discover the hop and to calculate a round trip time. Some systems use ICMP probes (ICMP Echo request packets) instead of UDP ones to implement traceroute. In both cases traceroute relies on the probes being rejected via an ICMP message to discover the hops taken along a path to the final destination. Both probe types, UDP and ICMP, are encapsulated into an IP packet and thus have a TTL field that can be used to cause a path rejection.

Implementations of the remote traceroute capability as defined within this memo SHOULD be done using UDP packets to a (hopefully) unused port. ICMP probes (ICMP Echo Request packets) SHOULD NOT be used. Many PC implementations of traceroute use the ICMP probe method, which they should not, since this implementation method has been known to have a high probability of failure. Intermediate hops become invisible when a router either refuses to send an ICMP TTL expired message in response to an incoming ICMP packet or simply tosses ICMP echo requests altogether.

The behavior of some routers not to return a TTL expired message in response to an ICMP Echo request is due in part to the following text extracted from RFC 792 [RFC792]:

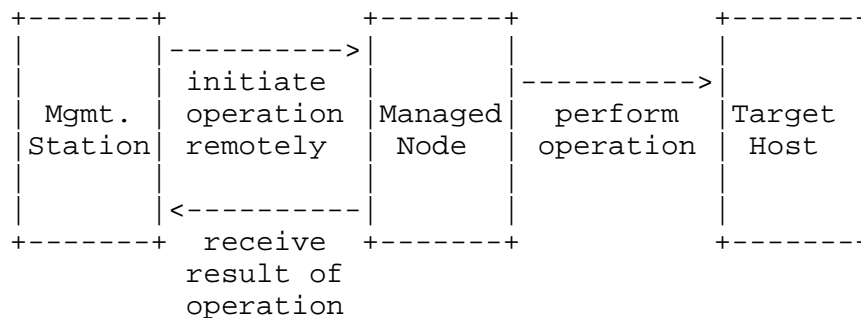

"The ICMP messages typically report errors in the processing of datagrams. To avoid the infinite regress of messages about messages etc., no ICMP messages are sent about ICMP messages."

### 1.3. Lookup

The Lookup operation enables remote lookup of addresses for a symbolic name as it is, for example, performed by functions `getnameinfo()` or `gethostbyaddr()` and lookup of symbolic names for an address as it is, for example, performed by functions `getaddrinfo()` or `gethostbyname()`. Note that whatever lookup function is chosen, results are not necessarily consistent with the results of a pure Domain Name Service (DNS) lookup, but may be influenced by local lookup tables or other sources of information. The lookup capability can be used to determine the symbolic name of a hop in a traceroute path. Also, the reverse lookup can be used, for example, for analyzing name lookup problems.

### 1.4. Remote Operations

The MIB modules defined in this document allow a management station to initiate ping, traceroute, and lookup operations remotely. The basic scenario is illustrated by the following diagram.

A management station is the local host from which the remote ping, traceroute, or Lookup operation is initiated using an SNMP request. The managed node is a remote host where the MIBs defined by this memo are implemented. It receives the remote operation via SNMP and performs the actual ping, traceroute, or lookup function.

## 2. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [RFC3410].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIV2, which is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].

### 3. Structure of the MIBs

This document defines three MIB modules:

- o DISMAN-PING-MIB  
Defines a ping MIB.
- o DISMAN-TRACEROUTE-MIB  
Defines a traceroute MIB.
- o DISMAN-NSLOOKUP-MIB

Provides access to lookup functions for symbolic names and addresses at a remote host provided, for example, by functions `getaddrinfo()/getnameinfo()` and `gethostbyname()/gethostbyaddr()`.

The ping and traceroute MIBs are structured to allow creation of ping or traceroute tests that can be set up to issue a series of operations periodically and to generate NOTIFICATIONS to report on test results. Many network administrators have in the past written UNIX shell scripts or command batch files to operate in a fashion similar to the functionality provided by the ping and traceroute MIBs defined within this memo. The intent of this document is to acknowledge the importance of these functions and to provide a standards-based solution.

#### 3.1. Ping MIB

The DISMAN-PING-MIB consists of the following components:

- o `pingMaxConcurrentRequests`
- o `pingCtlTable`
- o `pingResultsTable`
- o `pingProbeHistoryTable`

### 3.1.1. pingMaxConcurrentRequests

The object `pingMaxConcurrentRequests` enables control of the maximum number of concurrent active requests that an agent implementation supports. It is permissible for an agent either to limit the maximum upper range allowed for this object or to implement this object as read-only with an implementation limit expressed as its value.

### 3.1.2. pingCtlTable

A remote ping test is started by setting `pingCtlAdminStatus` to `enabled(1)`. The corresponding `pingCtlEntry` MUST have been created, and its `pingCtlRowStatus` set to `active(1)`, prior to starting the test. A single SNMP PDU can be used to create and start a remote ping test. Within the PDU, `pingCtlTargetAddress` should be set to the target host's address (`pingCtlTargetAddressType` will default to `ipv4(1)`), `pingCtlAdminStatus` to `enabled(1)`, and `pingCtlRowStatus` to `createAndGo(4)`.

The first index element, `pingCtlOwnerIndex`, is of type `SnmpAdminString`, a textual convention that allows for use of the SNMPv3 View-Based Access Control Model (RFC 3415 [RFC3415], VACM) and that allows a management application to identify its entries. The second index, `pingCtlTestName` (also an `SnmpAdminString`), enables the same management application to have multiple requests outstanding.

Using the maximum value for the parameters defined within a `pingEntry` can result in a single remote ping test's taking at most 15 minutes (`pingCtlTimeOut` times `pingCtlProbeCount`), plus whatever time it takes to send the ping request and to receive its response over the network from the target host. Use of the defaults for `pingCtlTimeOut` and `pingCtlProbeCount` yields a maximum of 3 seconds to perform a "normal" ping test.

A management application can delete an active remote ping request by setting the corresponding `pingCtlRowStatus` object to `destroy(6)`.

The contents of the `pingCtlTable` are preserved across reIPLs (Initial Program Loads) of its agent according the values of each of the `pingCtlStorageType` objects.

### 3.1.3. pingResultsTable

An entry in the `pingResultsTable` is created for a corresponding `pingCtlEntry` once the test defined by this entry is started.

### 3.1.4. pingProbeHistoryTable

The results of past ping probes are stored in this table on a per-pingCtlEntry basis. This table is initially indexed by pingCtlOwnerIndex and pingCtlTestName so that the results of a probe relate to the pingCtlEntry that caused it. The maximum number of entries stored in this table per pingCtlEntry is determined by the value of pingCtlMaxRows.

An implementation of this MIB will remove the oldest entry in the pingProbeHistoryTable of the corresponding entry in the pingCtlTable to allow the addition of a new entry once the number of rows in the pingProbeHistoryTable reaches the value specified by pingCtlMaxRows for the corresponding entry in the pingCtlTable. An implementation MUST start assigning pingProbeHistoryIndex values at 1 and wrap after exceeding the maximum possible value, as defined by the limit of this object ('ffffffff'h).

### 3.2. Traceroute MIB

The DISMAN-TRACEROUTE-MIB consists of the following components:

- o traceRouteMaxConcurrentRequests
- o traceRouteCtlTable
- o traceRouteResultsTable
- o traceRouteProbeHistoryTable
- o traceRouteHopsTable

#### 3.2.1. traceRouteMaxConcurrentRequests

The object traceRouteMaxConcurrentRequests enables control of the maximum number of concurrent active requests that an agent implementation supports. It is permissible for an agent either to limit the maximum upper range allowed for this object or to implement this object as read-only with an implementation limit expressed as its value.

#### 3.2.2. traceRouteCtlTable

A remote traceroute test is started by setting traceRouteCtlAdminStatus to enabled(1). The corresponding traceRouteCtlEntry MUST have been created, and its traceRouteCtlRowStatus set to active(1), prior to starting the test. A single SNMP PDU can be used to create and start a remote traceroute

test. Within the PDU, `traceRouteCtlTargetAddress` should be set to the target host's address (`traceRouteCtlTargetAddressType` will default to `ipv4(1)`), `traceRouteCtlAdminStatus` to `enabled(1)`, and `traceRouteCtlRowStatus` to `createAndGo(4)`.

The first index element, `traceRouteCtlOwnerIndex`, is of type `SnmpAdminString`, a textual convention that allows for use of the SNMPv3 View-Based Access Control Model (RFC 3415 [RFC3415], VACM) and that allows a management application to identify its entries. The second index, `traceRouteCtlTestName` (also an `SnmpAdminString`), enables the same management application to have multiple requests outstanding.

Traceroute has a much longer theoretical maximum time for completion than ping: basically, 42 hours and 30 minutes (the product of `traceRouteCtlTimeOut`, `traceRouteCtlProbesPerHop`, and `traceRouteCtlMaxTtl`) plus some network transit time! Use of the defaults defined within an `traceRouteCtlEntry` yields a maximum of 4 minutes and 30 seconds for a default traceroute operation. Clearly, 42 plus hours is too long to wait for a traceroute operation to be completed.

The maximum Time to Live (TTL) value in effect for traceroute determines how long the traceroute function will keep increasing the TTL value in the probe it transmits, hoping to reach the target host. The function ends whenever the maximum TTL is exceeded or the target host is reached. The object `traceRouteCtlMaxFailures` was created in order to impose a throttle for how long traceroute continues to increase the TTL field in a probe without receiving any kind of response (timeouts). It is RECOMMENDED that agent implementations impose a time limit for how long it allows a traceroute operation to take, relative to how the function is implemented. For example, an implementation that can't process multiple traceroute operations at the same time SHOULD impose a shorter maximum allowed time period.

A management application can delete an active remote traceroute request by setting the corresponding `traceRouteCtlRowStatus` object to `destroy(6)`.

The contents of the `traceRouteCtlTable` are preserved across reIPLs (Initial Program Loads) of its agent according to the values of each of the `traceRouteCtlStorageType` objects.

### 3.2.3. `traceRouteResultsTable`

An entry in the `traceRouteResultsTable` is created upon determining the results of a specific traceroute operation. Entries in this table relate back to the `traceRouteCtlEntry` that caused the

corresponding traceroute operation to occur. The objects `traceRouteResultsCurHopCount` and `traceRouteResultsCurProbeCount` can be examined to determine how far the current remote traceroute operation has reached.

#### 3.2.4. `traceRouteProbeHistoryTable`

The results of past traceroute probes can be stored in this table on a per-`traceRouteCtlEntry` basis. This table is initially indexed by `traceRouteCtlOwnerIndex` and `traceRouteCtlTestName` so that the results of a probe relate to the `traceRouteCtlEntry` that caused it. The number of entries stored in this table per `traceRouteCtlEntry` is determined by the value of `traceRouteCtlMaxRows`.

An implementation of this MIB will remove the oldest entry in the `traceRouteProbeHistoryTable` of the corresponding entry in the `traceRouteCtlTable` to allow the addition of a new entry once the number of rows in the `traceRouteProbeHistoryTable` reaches the value of `traceRouteCtlMaxRows` for the corresponding entry in the `traceRouteCtlTable`. An implementation **MUST** start assigning `traceRouteProbeHistoryIndex` values at 1 and wrap after exceeding the maximum possible value, as defined by the limit of this object ('ffffffff'h).

#### 3.2.5. `traceRouteHopsTable`

The current traceroute path can be stored in this table on a per-`traceRouteCtlEntry` basis. This table is initially indexed by `traceRouteCtlOwnerIndex` and `traceRouteCtlTestName` so that a traceroute path relates to the `traceRouteCtlEntry` that caused it. A third index, `traceRouteHopsHopIndex`, enables keeping one `traceRouteHopsEntry` per traceroute hop. Creation of `traceRouteHopsTable` entries is enabled by setting the corresponding `traceRouteCtlCreateHopsEntries` object to `true(1)`.

### 3.3. Lookup MIB

The DISMAN-NSLOOKUP-MIB consists of the following components:

- o `lookupMaxConcurrentRequests` and `lookupPurgeTime`
- o `lookupCtlTable`
- o `lookupResultsTable`

### 3.3.1. lookupMaxConcurrentRequests and lookupPurgeTime

The object `lookupMaxConcurrentRequests` enables control of the maximum number of concurrent active requests that an agent implementation is structured to support. It is permissible for an agent either to limit the maximum upper range allowed for this object or to implement this object as read-only with an implementation limit expressed as its value.

The object `lookupPurgeTime` provides a method for entries in the `lookupCtlTable` and `lookupResultsTable` to be automatically deleted after the corresponding operation is completed.

### 3.3.2. lookupCtlTable

A remote lookup operation is initiated by performing an SNMP SET request on `lookupCtlRowStatus`. A single SNMP PDU can be used to create and start a remote lookup operation. Within the PDU, `lookupCtlTargetAddress` should be set to the entity to be resolved (`lookupCtlTargetAddressType` will default to `ipv4(1)`) and `lookupCtlRowStatus` to `createAndGo(4)`. The object `lookupCtlOperStatus` can be examined to determine the state of a lookup operation. A management application can delete an active remote lookup request by setting the corresponding `lookupCtlRowStatus` object to `destroy(6)`.

An `lookupCtlEntry` is initially indexed by `lookupCtlOwnerIndex`, which is a type of `SnmpAdminString`, a textual convention that allows for use of the SNMPv3 View-Based Access Control Model (RFC 3415 [RFC3415],

VACM) and that also allows for a management application to identify its entries. The `lookupCtlOwnerIndex` portion of the index is then followed by `lookupCtlOperationName`. The `lookupCtlOperationName` index enables the same `lookupCtlOwnerIndex` entity to have multiple outstanding requests.

The value of `lookupCtlTargetAddressType` determines which lookup function to perform. Specification of `dns(16)` as the value of this index implies that a function such as `getaddrinfo()` or `gethostbyname()` should be performed to determine the numeric addresses associated with a symbolic name via `lookupResultsTable` entries. Use of a value of either `ipv4(1)` or `ipv6(2)` implies that a function such as `getnameinfo()` or `gethostbyaddr()` should be performed to determine the symbolic name(s) associated with a numeric address at a remote host.

### 3.3.3. lookupResultsTable

The lookupResultsTable is used to store the results of lookup operations. Results to be reported here SHOULD be results of a lookup function that is commonly used by applications at the managed node. This implies that results are not necessarily consistent with the results of a pure DNS lookup at the managed node, but may be influenced by local lookup tables or other sources of information, depending on the configuration of the managed node.

The lookupResultsTable is initially indexed by the same index elements that the lookupCtlTable contains (lookupCtlOwnerIndex and lookupCtlOperationName) but has a third index element, lookupResultsIndex (Unsigned32 textual convention), in order to associate multiple results with the same lookupCtlEntry.

A remote host can be multi-homed and can have multiple symbolic (DNS) names. Therefore, a lookup operation can return multiple IP addresses and multiple symbolic names.

If the lookup operation was performed for a certain address by using getnameinfo() or gethostbyaddr(), for example, then entries in the lookupResultsTable MUST be made for each host name returned. If the lookup operation identifies one hostname as the host's 'official host name', then this name MUST be assigned a lookupResultsIndex of 1.

If a lookup operation was performed for a certain symbolic name by using getaddrinfo() or gethostbyname(), for example, then entries in the lookupResultsTable MUST be made for each address returned. The entries MUST be stored in the order that they are retrieved. Values assigned to lookupResultsIndex MUST start at 1 and increase in order.

An implementation SHOULD NOT retain SNMP-created entries in the lookupResultsTable across reIPLs (Initial Program Loads) of its agent, since management applications need to see consistent behavior with respect to the persistence of the table entries that they create.

### 3.4. Conformance

Each of the three MIB modules defined in this document has two current compliance statements, one for full compliance and one for minimum compliance. The minimum compliance statements are intended to be applied to implementation for devices with very limited resources. The main difference between full and minimum compliance is that for minimum compliance, dynamic creation and deletion of table entries is not required, whereas it is required for full compliance.

In addition, the DISMAN-PING-MIB module and the DISMAN-TRACEROUTE-MIB modules each have a deprecated compliance statement that was current in RFC 2925. Semantically, the new full compliance statements are identical to the deprecated ones. But some of the object groups used in the old compliance statements needed to be split in order to support the new minimal compliance statements.

#### 4. Definitions

The following MIB modules import from [RFC2863], [RFC3411], and [RFC4001]. They also use the REFERENCE clause to reference [RFC1812], [RFC2474], and [RFC3260].

#### DESCRIPTION

"The Ping MIB (DISMAN-PING-MIB) provides the capability of controlling the use of the ping function at a remote host.

Copyright (C) The Internet Society (2006). This version of this MIB module is part of RFC 4560; see the RFC itself for full legal notices."

#### -- Revision history

REVISION "200606130000Z" -- 13 June 2006

#### DESCRIPTION

"Updated version, published as RFC 4560.

- Correctly considered IPv6 in DESCRIPTION clause of pingCtlDataSize
- Replaced references to RFC 2575 by RFC 3415
- Replaced references to RFC 2571 by RFC 3411
- Replaced references to RFC 2851 by RFC 4001
- Added DEFVAL { {} } to definition of pingCtlTrapGeneration
- Changed DEFVAL of object pingCtlDescr from DEFVAL { '00'H } to DEFVAL { ''H }
- Changed DEFVAL of object pingCtlSourceAddressType from DEFVAL { ipv4 } to DEFVAL { unknown }
- Extended DESCRIPTION clause of pingResultsTable describing re-initialization of entries
- Changed SYNTAX of pingResultsProbeResponses and pingResultsSentProbes from Unsigned32 to Gauge32
- Changed status of pingCompliance to deprecated
- Added pingFullCompliance and pingMinimumCompliance
- Changed status of pingGroup and pingTimeStampGroup to deprecated
- Added pingMinimumGroup, pingCtlRowStatusGroup, and pingHistoryGroup"

REVISION "200009210000Z" -- 21 September 2000

#### DESCRIPTION

"Initial version, published as RFC 2925."

::= { mib-2 80 }

#### -- Textual Conventions

OperationResponseStatus ::= TEXTUAL-CONVENTION

STATUS current

DESCRIPTION

"Used to report the result of an operation:

responseReceived(1) - Operation is completed successfully.  
 unknown(2) - Operation failed due to unknown error.  
 internalError(3) - An implementation detected an error  
     in its own processing that caused an operation  
     to fail.  
 requestTimedOut(4) - Operation failed to receive a  
     valid reply within the time limit imposed on it.  
 unknownDestinationAddress(5) - Invalid destination  
     address.  
 noRouteToTarget(6) - Could not find a route to target.  
 interfaceInactiveToTarget(7) - The interface to be  
     used in sending a probe is inactive, and an  
     alternate route does not exist.  
 arpFailure(8) - Unable to resolve a target address to a  
     media-specific address.  
 maxConcurrentLimitReached(9) - The maximum number of  
     concurrent active operations would have been exceeded  
     if the corresponding operation was allowed.  
 unableToResolveDnsName(10) - The DNS name specified was  
     unable to be mapped to an IP address.  
 invalidHostAddress(11) - The IP address for a host  
     has been determined to be invalid. Examples of this  
     are broadcast or multicast addresses."

pingCtlOwnerIndex OBJECT-TYPE

SYNTAX SnmpAdminString (SIZE(0..32))

MAX-ACCESS not-accessible

STATUS current

DESCRIPTION

"To facilitate the provisioning of access control by a security administrator using the View-Based Access Control Model (RFC 2575, VACM) for tables in which multiple users may need to create or modify entries independently, the initial index is used as an 'owner index'. Such an initial index has a syntax of SnmpAdminString and can thus be trivially mapped to a securityName or groupName defined in VACM, in accordance with a security policy.

When used in conjunction with such a security policy, all entries in the table belonging to a particular user (or group) will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same subidentifiers (except for the 'column' subidentifier) up to the end of the encoded owner index. To configure VACM to permit access to this portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask 'wildcarding' the column subidentifier. More elaborate configurations are possible."

**pingCtlByPassRouteTable OBJECT-TYPE**

SYNTAX            TruthValue  
MAX-ACCESS       read-create  
STATUS            current

**DESCRIPTION**

"The purpose of this object is to enable optional bypassing the route table. If enabled, the remote host will bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly attached network, an error is returned. This option can be used to perform the ping operation to a local host through an interface that has no route defined (e.g., after the interface was dropped by the routing daemon at the host)."

```
DEFVAL { false }  
::= { pingCtlEntry 21 }
```

pingCtlDSField OBJECT-TYPE

SYNTAX Unsigned32 (0..255)

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"Specifies the value to store in the Type of Service (TOS) octet in the IPv4 header or in the Traffic Class octet in the IPv6 header, respectively, of the IP packet used to encapsulate the ping probe.

The octet to be set in the IP header contains the Differentiated Services (DS) Field in the six most significant bits.

This option can be used to determine what effect an explicit DS Field setting has on a ping response. Not all values are legal or meaningful. A value of 0 means that the function represented by this option is not supported. DS Field usage is often not supported by IP implementations, and not all values are supported. Refer to RFC 2474 and RFC 3260 for guidance on usage of this field."

REFERENCE

"Refer to RFC 1812 for the definition of the IPv4 TOS octet and to RFC 2460 for the definition of the IPv6 Traffic Class octet. Refer to RFC 2474 and RFC 3260 for the definition of the Differentiated Services Field."

```
DEFVAL { 0 }  
::= { pingCtlEntry 22 }
```

pingCtlRowStatus OBJECT-TYPE

SYNTAX RowStatus

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"This object allows entries to be created and deleted in the pingCtlTable. Deletion of an entry in this table results in the deletion of all corresponding (same pingCtlOwnerIndex and pingCtlTestName index values) pingResultsTable and pingProbeHistoryTable entries.

A value MUST be specified for pingCtlTargetAddress prior to acceptance of a transition to active(1) state.

When a value for pingCtlTargetAddress is set,

the value of object pingCtlRowStatus changes from notReady(3) to notInService(2).

Activation of a remote ping operation is controlled via pingCtlAdminStatus, not by changing this object's value to active(1).

Transitions in and out of active(1) state are not allowed while an entry's pingResultsOperStatus is active(1), with the exception that deletion of an entry in this table by setting its RowStatus object to destroy(6) will stop an active ping operation.

The operational state of a ping operation can be determined by examination of its pingResultsOperStatus object."

#### REFERENCE

"See definition of RowStatus in RFC 2579, 'Textual Conventions for SMIV2.'"

::= { pingCtlEntry 23 }

#### -- Ping Results Table

##### pingResultsTable OBJECT-TYPE

SYNTAX SEQUENCE OF PingResultsEntry

MAX-ACCESS not-accessible

STATUS current

##### DESCRIPTION

"Defines the Ping Results Table for providing the capability of performing ping operations at a remote host. The results of these operations are stored in the pingResultsTable and the pingProbeHistoryTable.

An entry is added to the pingResultsTable when an pingCtlEntry is started by successful transition of its pingCtlAdminStatus object to enabled(1).

If the object pingCtlAdminStatus already has the value enabled(1), and if the corresponding pingResultsOperStatus object has the value completed(3), then successfully writing enabled(1) to object pingCtlAdminStatus re-initializes the already existing entry in the pingResultsTable. The values of objects in the re-initialized entry are the same as the values of objects in a new entry would be.

An entry is removed from the pingResultsTable when its corresponding pingCtlEntry is deleted."

```

REVISION "200606130000Z" -- 13 June 2006

DESCRIPTION

"Updated version, published as RFC 4560.

- Correctly considered IPv6 in DESCRIPTION clause of object traceRouteCtlDataSize
- Replaced references to RFC 2575 by RFC 3415
- Replaced references to RFC 2571 by RFC 3411
- Replaced references to RFC 2851 by RFC 4001
- Clarified DESCRIPTION clause of object traceRouteResultsLastGoodPath
- Changed range of object traceRouteCtlInitialTtl from (0..255) to (1..255)
- Extended DESCRIPTION clause of traceRouteResultsTable describing re-initialization of entries
- Changed SYNTAX of traceRouteResultsTestAttempts and traceRouteResultsTestSuccesses from Unsigned32 to Gauge32
- Changed status of traceRouteCompliance to deprecated
- Added traceRouteFullCompliance and traceRouteMinimumCompliance
- Changed status of traceRouteGroup and traceRouteTimeStampGroup to deprecated
- Added traceRouteMinimumGroup, traceRouteCtlRowStatusGroup, and traceRouteHistoryGroup
- Changed DEFVAL of object traceRouteCtlTargetAddressType from { ipv4 } to { unknown }
- Changed DEFVAL of object traceRouteCtlDescr from { '00'H } to { ''H }
- Added DEFVAL for object traceRouteCtlTrapGeneration of DEFVAL { { } }

REVISION "200009210000Z" -- 21 September 2000

 STATUS current  
 DESCRIPTION

"To facilitate the provisioning of access control by a security administrator using the View-Based Access Control Model (RFC 3415, VACM) for tables in which multiple users may need to create or modify entries independently, the initial index is used as an 'owner index'. Such an initial index has a syntax of SnmpAdminString and can thus be trivially mapped to a securityName or groupName defined in VACM, in accordance with a security policy.

When used in conjunction with such a security policy, all entries in the table belonging to a particular user (or group) will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same subidentifiers (except for the 'column' subidentifier) up to the end of the encoded owner index. To configure VACM to permit access to this portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask 'wildcarding' the column subidentifier. More elaborate configurations are possible."

"Specifies the host address used on the traceroute request at the remote host. The host address type can be determined by examining the value of the corresponding traceRouteCtlTargetAddressType.

A value for this object MUST be set prior to transitioning its corresponding traceRouteCtlEntry to active(1) via traceRouteCtlRowStatus."

`::= { traceRouteCtlEntry 4 }``traceRouteCtlByPassRouteTable OBJECT-TYPE``SYNTAX TruthValue``MAX-ACCESS read-create``STATUS current``DESCRIPTION`

"The purpose of this object is to enable optional bypassing the route table. If enabled, the remote host will bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly attached network, an error is returned. This option can be used to perform the traceroute operation to a local host through an interface that has no route defined (e.g., after the interface was dropped by the routing daemon at the host)."

`DEFVAL { false }``::= { traceRouteCtlEntry 5 }``traceRouteCtlDataSize OBJECT-TYPE``SYNTAX Unsigned32 (0..65507)``UNITS "octets"``MAX-ACCESS read-create``STATUS current``DESCRIPTION`

"Specifies the size of the data portion of a traceroute request, in octets. If the RECOMMENDED traceroute method (UDP datagrams as probes) is used, then the value contained in this object MUST be applied. If another traceroute method is used for which the specified size is not appropriate, then the implementation SHOULD use whatever size (appropriate to the method) is closest to the specified size.

The maximum value for this object was computed by subtracting the smallest possible IP header size of 20 octets (IPv4 header with no options) and the UDP header size of 8 octets from the maximum IP packet size. An IP packet has a maximum size of 65535 octets (excluding IPv6 Jumbograms)."

traceRouteCtlDSField OBJECT-TYPE  
SYNTAX Unsigned32 (0..255)  
MAX-ACCESS read-create  
STATUS current

DESCRIPTION  
    "Specifies the value to store in the Type of Service (TOS) octet in the IPv4 header or in the Traffic Class octet in the IPv6 header, respectively, of the IP packet used to encapsulate the traceroute probe.  
  
    The octet to be set in the IP header contains the Differentiated Services (DS) Field in the six most significant bits.  
  
    This option can be used to determine what effect an explicit DS Field setting has on a traceroute response. Not all values are legal or meaningful. A value of 0 means that the function represented by this option is not supported. DS Field usage is often not supported by IP implementations, and not all values are supported. Refer to RFC 2474 and RFC 3260 for guidance on usage of this field."

REFERENCE  
    "Refer to RFC 1812 for the definition of the IPv4 TOS octet and to RFC 2460 for the definition of the IPv6 Traffic Class octet. Refer to RFC 2474 and RFC 3260 for the definition of the Differentiated Services Field."

SYNTAX      OBJECT IDENTIFIER
MAX-ACCESS  read-create
STATUS      current
DESCRIPTION
    "The value of this object is used either to report or to
    select the implementation method to be used for
    performing a traceroute operation. The value of this
    object may be selected from
    traceRouteImplementationTypeDomains.

    Additional implementation types should be allocated as
    required by implementers of the DISMAN-TRACEROUTE-MIB
    under their enterprise specific registration point,
    not beneath traceRouteImplementationTypeDomains."
DEFVAL { traceRouteUsingUdpProbes }
::= { traceRouteCtlEntry 26 }

```

#### traceRouteCtlRowStatus OBJECT-TYPE

```

SYNTAX      RowStatus
MAX-ACCESS  read-create
STATUS      current
DESCRIPTION
    "This object allows entries to be created and deleted
    in the traceRouteCtlTable. Deletion of an entry in
    this table results in a deletion of all corresponding (same
    traceRouteCtlOwnerIndex and traceRouteCtlTestName
    index values) traceRouteResultsTable,
    traceRouteProbeHistoryTable, and traceRouteHopsTable
    entries.

```

A value MUST be specified for traceRouteCtlTargetAddress prior to acceptance of a transition to active(1) state.

When a value for pingCtlTargetAddress is set, the value of object pingCtlRowStatus changes from notReady(3) to notInService(2).

Activation of a remote traceroute operation is controlled via traceRouteCtlAdminStatus, and not by transitioning of this object's value to active(1).

Transitions in and out of active(1) state are not allowed while an entry's traceRouteResultsOperStatus is active(1), with the exception that deletion of an entry in this table by setting its RowStatus object to destroy(6) will stop an active traceroute operation.

The operational state of an traceroute operation can be determined by examination of the corresponding traceRouteResultsOperStatus object."

## DESCRIPTION

"The Lookup MIB (DISMAN-NSLOOKUP-MIB) enables determination of either the name(s) corresponding to a host address or of the address(es) associated with a host name at a remote host.

Copyright (C) The Internet Society (2006). This version of this MIB module is part of RFC 4560; see the RFC itself for full legal notices."

## -- Revision history

REVISION "200606130000Z" -- 13 June 2006

## DESCRIPTION

"Updated version, published as RFC 4560.

- Replaced references to RFC 2575 by RFC 3415
- Replaced references to RFC 2571 by RFC 3411
- Replaced references to RFC 2851 by RFC 4001
- Added value enabled(1) to SYNTAX clause of lookupCtlOperStatus
- Added lookupMinimumCompliance
- Defined semantics of value 0 for object lookupPurgeTime
- Added DEFVAL { unknown } to object lookupCtlTargetAddressType OBJECT-TYPE"

REVISION "200009210000Z" -- 21 September 2000

## DESCRIPTION

## lookupPurgeTime OBJECT-TYPE

SYNTAX           Unsigned32 (0..86400)  
 UNITS            "seconds"  
 MAX-ACCESS       read-write  
 STATUS           current

## DESCRIPTION

"The amount of time to wait before automatically deleting an entry in the lookupCtlTable and any dependent lookupResultsTable entries after the lookup operation represented by a lookupCtlEntry has been completed. A lookupCtlEntry is considered complete when its lookupCtlOperStatus object has a value of completed(3).

A value of 0 indicates that automatic deletion of entries is disabled."

DEFVAL { 900 } -- 15 minutes as default  
 ::= { lookupObjects 2 }

## -- Lookup Control Table

## lookupCtlTable OBJECT-TYPE

SYNTAX           SEQUENCE OF LookupCtlEntry  
 MAX-ACCESS       not-accessible  
 STATUS           current

## DESCRIPTION

"Defines the Lookup Control Table for providing the capability of performing a lookup operation for a symbolic host name or for a host address from a remote host."

```
::= { lookupObjects 3 }
```

```
lookupCtlEntry OBJECT-TYPE
```

```
SYNTAX          LookupCtlEntry
```

```
MAX-ACCESS      not-accessible
```

```
STATUS          current
```

```
DESCRIPTION
```

"Defines an entry in the lookupCtlTable. A lookupCtlEntry is initially indexed by lookupCtlOwnerIndex, which is a type of SnmpAdminString, a textual convention that allows for the use of the SNMPv3 View-Based Access Control Model (RFC 3415, VACM) and that also allows a management application to identify its entries. The second index element, lookupCtlOperationName, enables the same lookupCtlOwnerIndex entity to have multiple outstanding requests. The value of lookupCtlTargetAddressType determines which lookup function to perform."

```

```

```
MAX-ACCESS      not-accessible
```

```
STATUS          current
```

```
DESCRIPTION
```

"To facilitate the provisioning of access control by a security administrator using the View-Based Access Control Model (RFC 2575, VACM) for tables in which multiple users may need to create or modify entries independently, the initial index is used as an 'owner index'. Such an initial index has a syntax of SnmpAdminString and can thus be trivially mapped to a

securityName or groupName defined in VACM, in accordance with a security policy.

When used in conjunction with such a security policy all entries in the table belonging to a particular user (or group) will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same subidentifiers (except for the 'column' subidentifier) up to the end of the encoded owner index. To configure VACM to permit access to this portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask 'wildcarding' the column subidentifier. More elaborate configurations are possible."

```
::= { lookupCtlEntry 1 }
```

lookupCtlOperationName OBJECT-TYPE

SYNTAX SnmpAdminString (SIZE(0..32))

MAX-ACCESS not-accessible

STATUS current

DESCRIPTION

"The name of a lookup operation. This is locally unique, within the scope of an lookupCtlOwnerIndex."

```
::= { lookupCtlEntry 2 }
```

lookupCtlTargetAddressType OBJECT-TYPE

SYNTAX InetAddressType

MAX-ACCESS read-create

STATUS current

DESCRIPTION

"Specifies the type of address for performing a lookup operation for a symbolic host name or for a host address from a remote host.

Specification of dns(16) as the value for this object means that a function such as, for example, getaddrinfo() or gethostbyname() should be performed to return one or more numeric addresses. Use of a value of either ipv4(1) or ipv6(2) means that a functions such as, for example, getnameinfo() or gethostbyaddr() should be used to return the symbolic names associated with a host."

DEFVAL { unknown }

```
::= { lookupCtlEntry 3 }
```

## lookupCtlTargetAddress OBJECT-TYPE

SYNTAX InetAddress

MAX-ACCESS read-create

STATUS current

## DESCRIPTION

"Specifies the address used for a resolver lookup at a remote host. The corresponding lookupCtlTargetAddressType objects determines its type, as well as the function that can be requested.

A value for this object MUST be set prior to transitioning its corresponding lookupCtlEntry to active(1) via lookupCtlRowStatus."

::= { lookupCtlEntry 4 }

## lookupCtlOperStatus OBJECT-TYPE

SYNTAX INTEGER {  
     enabled(1),      -- operation is active  
     notStarted(2), -- operation has not started  
     completed(3)    -- operation is done  
 }

MAX-ACCESS read-only

STATUS current

## DESCRIPTION

"Reflects the operational state of an lookupCtlEntry:

enabled(1)      - Operation is active.  
 notStarted(2) - Operation has not been enabled.  
 completed(3)   - Operation has been completed.

An operation is automatically enabled(1) when its lookupCtlRowStatus object is transitioned to active(1) status. Until this occurs, lookupCtlOperStatus MUST report a value of notStarted(2). After the lookup operation is completed (success or failure), the value for lookupCtlOperStatus MUST be transitioned to completed(3)."

::= { lookupCtlEntry 5 }

## lookupCtlTime OBJECT-TYPE

SYNTAX Unsigned32

UNITS "milliseconds"

MAX-ACCESS read-only

STATUS current

## DESCRIPTION

"Reports the number of milliseconds that a lookup operation required to be completed at a remote host. Completed means operation failure as well as

```

        success."
 ::= { lookupCtlEntry 6 }

```

#### lookupCtlRc OBJECT-TYPE

SYNTAX Integer32

MAX-ACCESS read-only

STATUS current

#### DESCRIPTION

"The system-specific return code from a lookup operation. All implementations MUST return a value of 0 for this object when the remote lookup operation succeeds. A non-zero value for this objects indicates failure. It is recommended that implementations return the error codes that are generated by the lookup function used."

```

 ::= { lookupCtlEntry 7 }

```

#### lookupCtlRowStatus OBJECT-TYPE

SYNTAX RowStatus

MAX-ACCESS read-create

STATUS current

#### DESCRIPTION

"This object allows entries to be created and deleted in the lookupCtlTable.

A remote lookup operation is started when an entry in this table is created via an SNMP set request and the entry is activated. This occurs by setting the value of this object to CreateAndGo(4) during row creation or by setting this object to active(1) after the row is created.

A value MUST be specified for lookupCtlTargetAddress prior to the acceptance of a transition to active(1) state. A remote lookup operation starts when its entry first becomes active(1). Transitions in and out of active(1) state have no effect on the operational behavior of a remote lookup operation, with the exception that deletion of an entry in this table by setting its RowStatus object to destroy(6) will stop an active remote lookup operation.

The operational state of a remote lookup operation can be determined by examination of its lookupCtlOperStatus object."

#### REFERENCE

```
"See definition of RowStatus in RFC 2579,  
'Textual Conventions for SMIV2.'"
 ::= { lookupCtlEntry 8 }
```

#### -- Lookup Results Table

lookupResultsTable OBJECT-TYPE

SYNTAX SEQUENCE OF LookupResultsEntry

MAX-ACCESS not-accessible

STATUS current

DESCRIPTION

"Defines the Lookup Results Table for providing the capability of determining the results of a operation at a remote host.

One or more entries are added to the lookupResultsTable when a lookup operation, as reflected by an lookupCtlEntry, is completed successfully. All entries related to a successful lookup operation MUST be added to the lookupResultsTable at the same time that the associating lookupCtlOperStatus object is transitioned to completed(2).

The number of entries added depends on the results determined for a particular lookup operation. All entries associated with an lookupCtlEntry are removed when the lookupCtlEntry is deleted.

A remote host can be multi-homed and have more than one IP address associated with it (returned by lookup function), or it can have more than one symbolic name (returned by lookup function).

A function such as, for example, getnameinfo() or gethostbyaddr() is called with a host address as its parameter and is used primarily to determine a symbolic name to associate with the host address. Entries in the lookupResultsTable MUST be made for each host name returned. If the function identifies an 'official host name,' then this symbolic name MUST be assigned a lookupResultsIndex of 1.

A function such as, for example, getaddrinfo() or gethostbyname() is called with a symbolic host name and is used primarily to retrieve a host address. The entries

MUST be stored in the order that they are retrieved from the lookup function. lookupResultsIndex 1 MUST be assigned to the first entry."

```
::= { lookupObjects 4 }
```

#### lookupResultsEntry OBJECT-TYPE

SYNTAX LookupResultsEntry

MAX-ACCESS not-accessible

STATUS current

#### DESCRIPTION

"Defines an entry in the lookupResultsTable. The first two index elements identify the lookupCtlEntry that a lookupResultsEntry belongs to. The third index element selects a single lookup operation result."

```
INDEX {
    lookupCtlOwnerIndex,
    lookupCtlOperationName,
    lookupResultsIndex
}
```

```
::= { lookupResultsTable 1 }
```

#### LookupResultsEntry ::=

```
SEQUENCE {
    lookupResultsIndex      Unsigned32,
    lookupResultsAddressType InetAddressType,
    lookupResultsAddress    InetAddress
}
```

#### lookupResultsIndex OBJECT-TYPE

SYNTAX Unsigned32 (1..'ffffffff'h)

MAX-ACCESS not-accessible

STATUS current

#### DESCRIPTION

"Entries in the lookupResultsTable are created when the result of a lookup operation is determined.

Entries MUST be stored in the lookupResultsTable in the order that they are retrieved. Values assigned to lookupResultsIndex MUST start at 1 and increase consecutively."

```
::= { lookupResultsEntry 1 }
```

#### lookupResultsAddressType OBJECT-TYPE

SYNTAX InetAddressType

MAX-ACCESS read-only

STATUS current

#### DESCRIPTION

"Indicates the type of result of a remote lookup operation. A value of unknown(0) implies either that the operation hasn't been started or that it has failed."

```
::= { lookupResultsEntry 2 }
```

#### lookupResultsAddress OBJECT-TYPE

SYNTAX InetAddress

MAX-ACCESS read-only

STATUS current

DESCRIPTION

"Reflects a result for a remote lookup operation as per the value of lookupResultsAddressType."

The address type (InetAddressType) that relates to this object is specified by the corresponding value of lookupResultsAddress."

```
::= { lookupResultsEntry 3 }
```

    STATUS current
    DESCRIPTION
        "The group of objects that constitute the remote
        Lookup operation."
    ::= { lookupGroups 1 }

```

END

## 5. Security Considerations

There are a number of management objects defined in the three MIB modules with a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations. These are the tables and objects and their sensitivity/vulnerability:

- o pingMaxConcurrentRequests
  - o traceRouteMaxConcurrentRequests
  - o lookupMaxConcurrentRequests
- The MIB modules limit their maximum numbers of concurrent requests by the values of these objects. Unauthorized access to them may lead to an overload of the managed node and to a disruption of other functions of the managed node.
- o pingCtlTable
  - o traceRouteCtlTable
  - o lookupCtlTable
- All objects in entries of these tables (except index objects) have a MAX-ACCESS clause of read-create. Unauthorized access to these objects can disturb the measurements controlled by the tables. Also, the functions offered by the MIB modules can be misused for illegal data retrieval and for attacking other systems by floods of ping probes, traceroute probes or lookup requests, respectively.

In general, all three, the ping, traceroute, and lookup functions, when used excessively are considered a form of system attack. In the case of ping, sending a system request too often can negatively effect its performance and attempting to connect to what is supposed to be an unused port can be very unpredictable. Excessive use of the traceroute capability can, like ping, negatively affect system performance. The same applies to excessive use of the lookup service, particularly if the lookup cannot be resolved locally. In

insecure environments, it is RECOMMENDED that the MIBs defined within this memo not be supported.

- o lookupPurgeTime

Unauthorized access to this object can lead to the deletion of results of lookup operations before they are read by a management system, if the object is set to 0 or small values close to 0. If the object is set to very high values, unauthorized access can lead to a high consumption of resources for storing lookup results.

Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus important to control even GET and/or NOTIFY access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP. However, the only information that can be disclosed without encryption is the configuration and results of measurements that are performed by implementations of the MIB modules.

To facilitate the provisioning of access control by a security administrator using the View-Based Access Control Model (VACM), defined in RFC 3415 [RFC3415], for tables in which multiple users may need to create or modify entries independently, the initial index is used as an "owner index." Such an initial index has a syntax of SnmpAdminString and can thus be trivially mapped to a securityName or groupName defined in VACM, in accordance with a security policy.

All entries in related tables belonging to a particular user will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same subidentifiers (except for the "column" subidentifier) up to the end of the encoded owner index. To configure VACM to permit access to this portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask 'wildcarding' the column subidentifier. More elaborate configurations are possible. The VACM access control mechanism described above provides control.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPSec), even then, there is no control as to who on the secure network is

allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module.

It is RECOMMENDED that implementers consider the security features as provided by the SNMPv3 framework (see [RFC3410], section 8), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy).

Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP entity giving access to an instance of this MIB module is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.
